

# Cumulative Impacts of Multiple Stressors on Stream Ecosystems: Periphyton Communities as Bioindicators

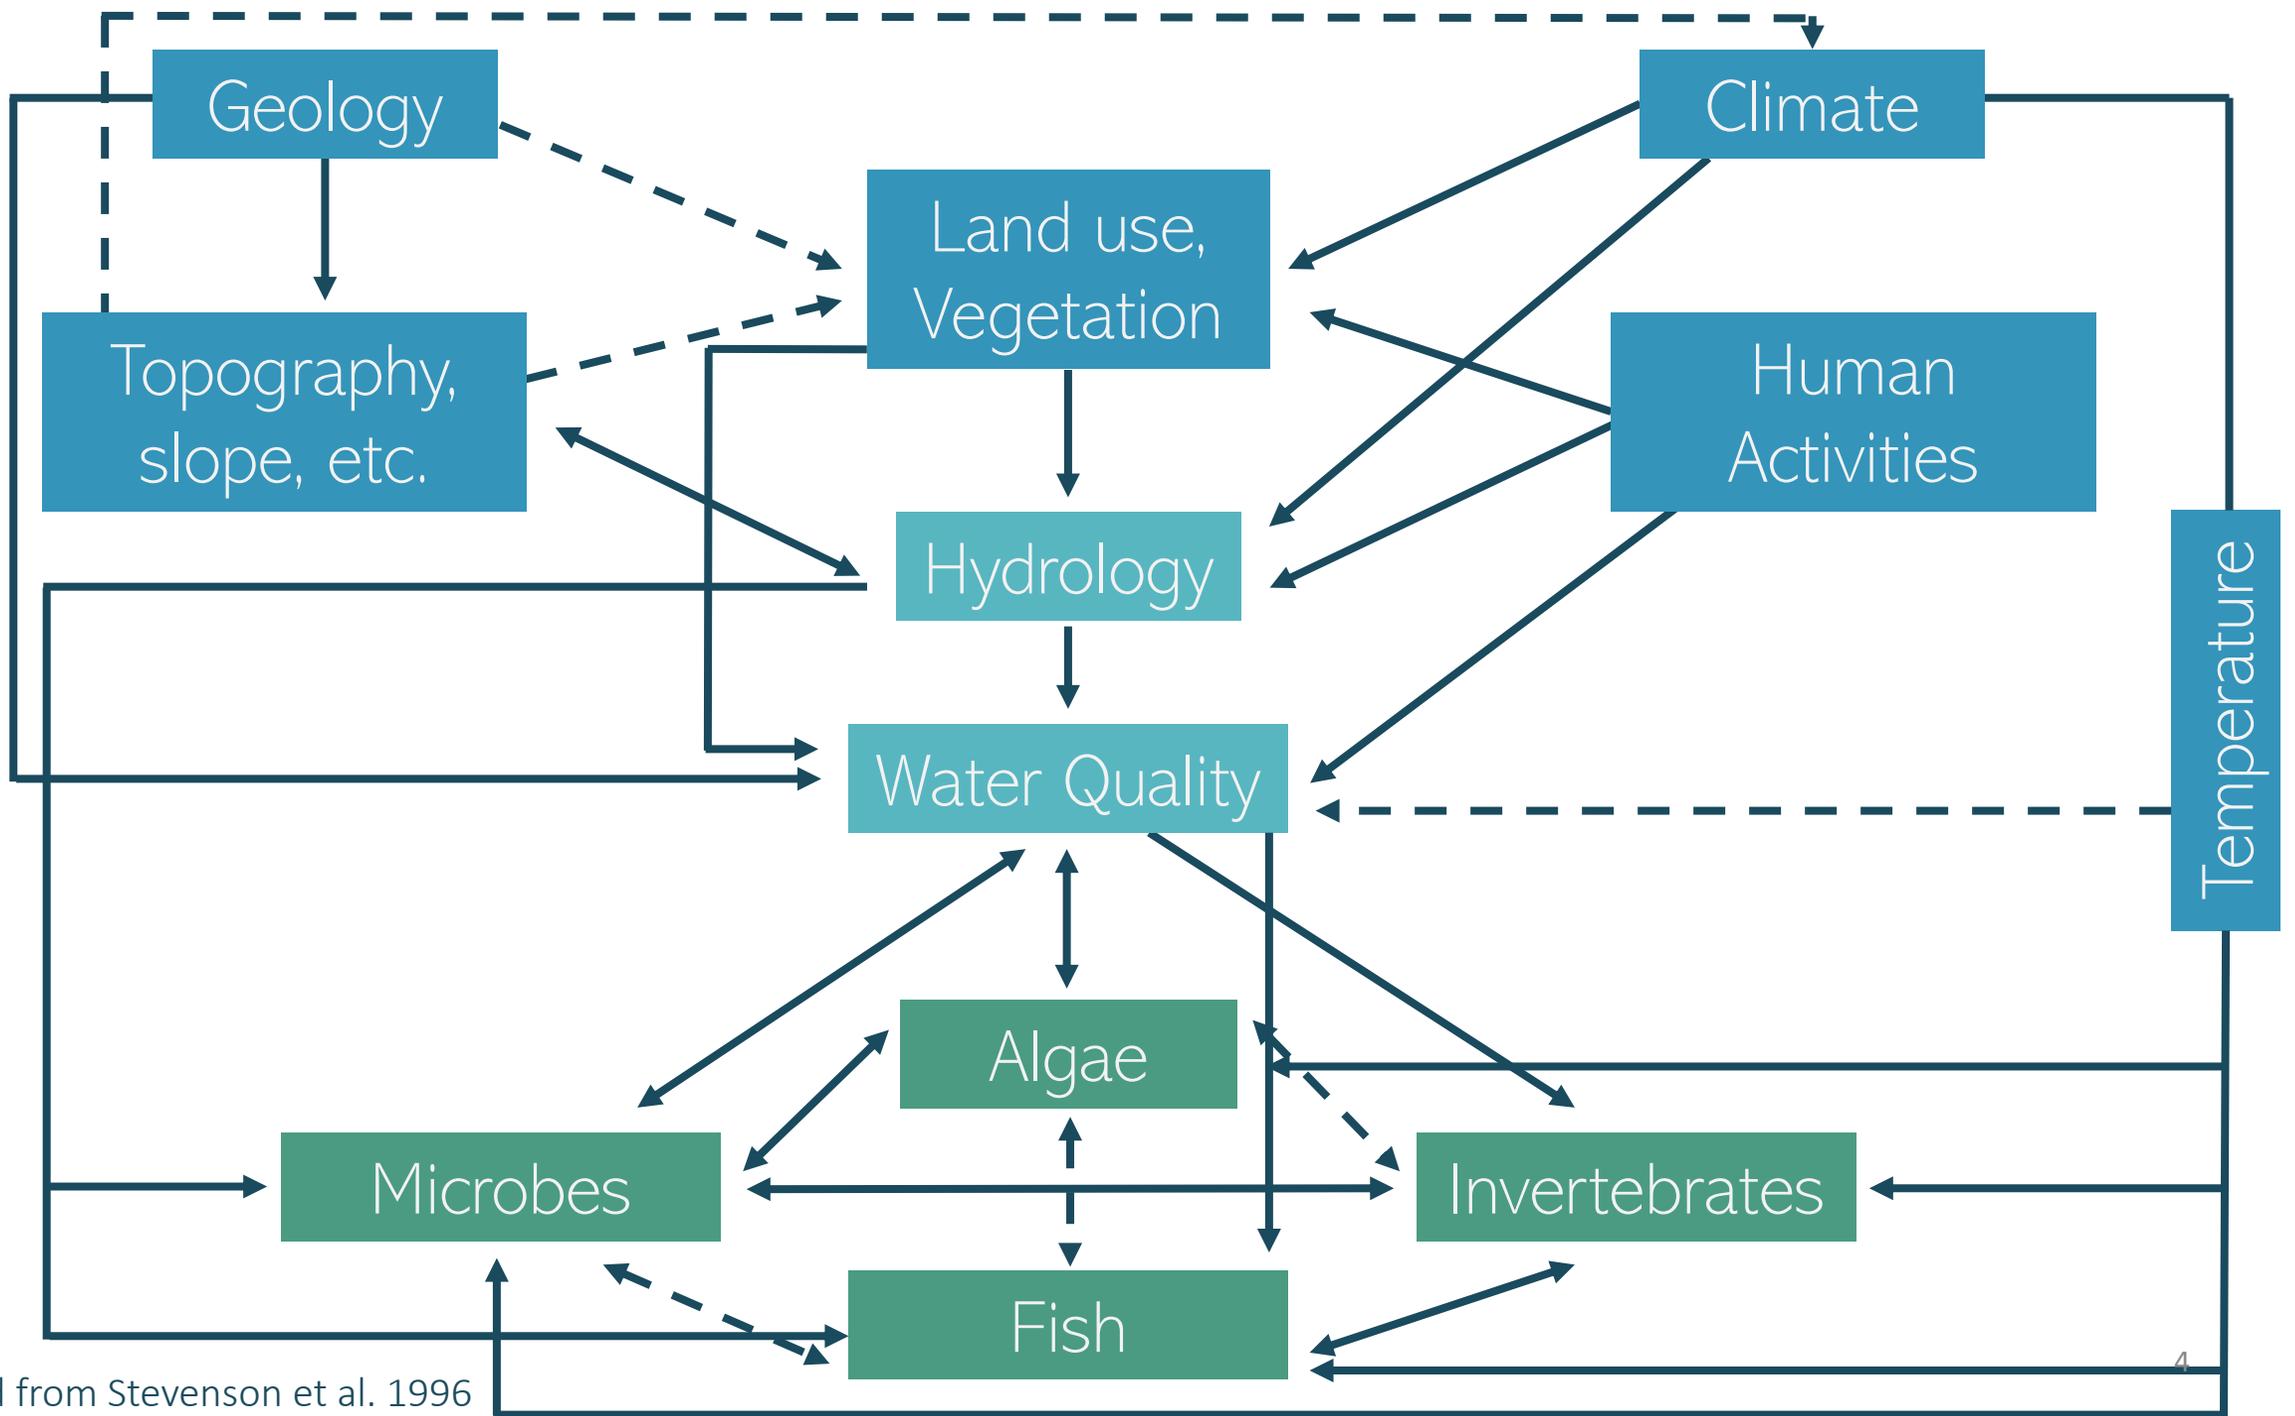

Shelby Stenerson, Rolf Vinebrooke, Jenna Cook, Blake Stuparyk, Jillian Lightbown, Craig Emmerton, Mark Graham, Faye Wyatt, Cristina Buendia-Fores, and Mina Nasr

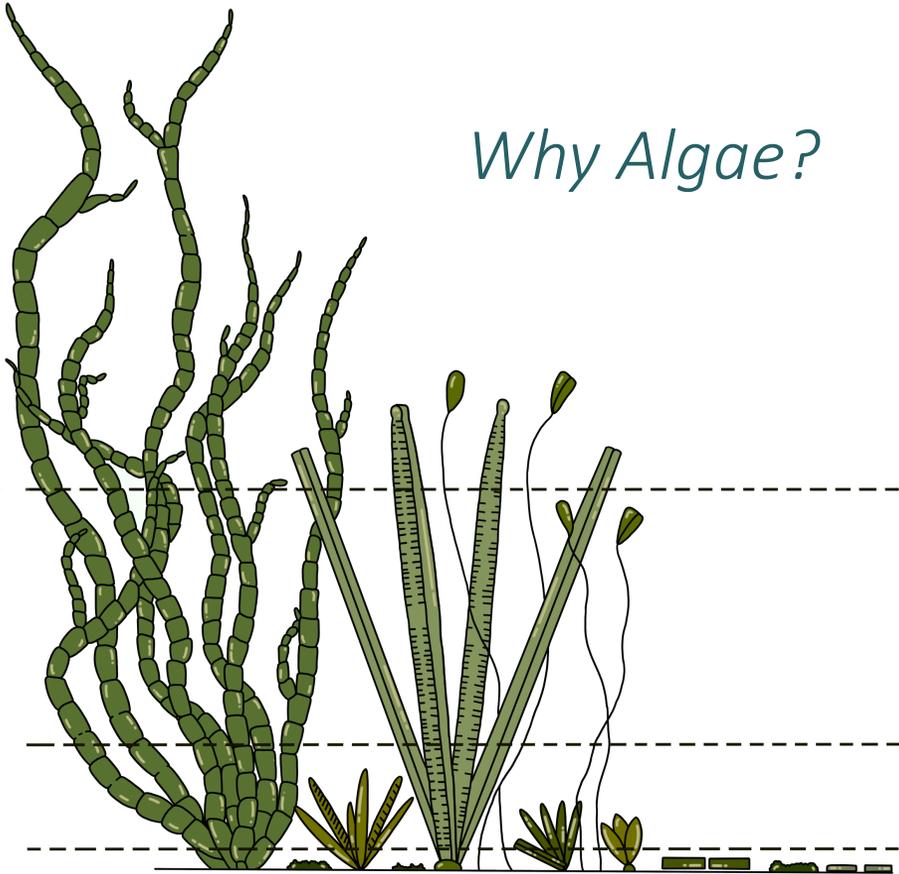

# *An Introduction to Bioindicators*

Bioindicators include biological processes, species, or communities and are used to assess the quality of the environment and how it changes over time.

# An Introduction to Bioindicators

## Why Algae?

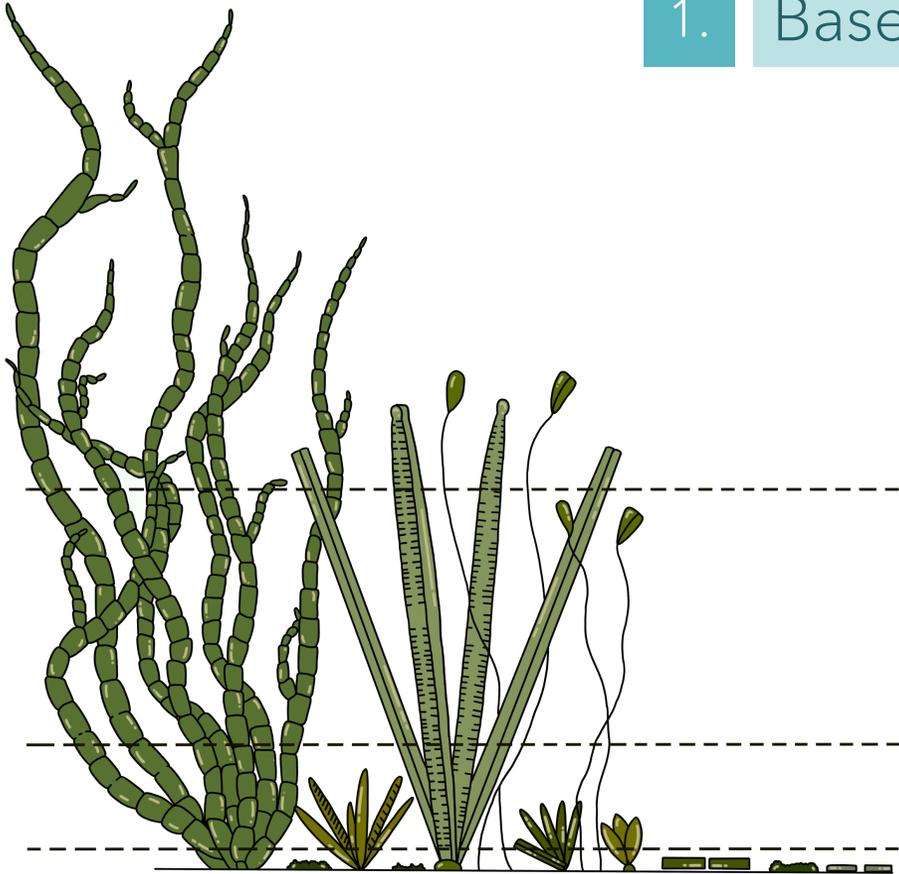

Modified from Hoagland et al. 1982

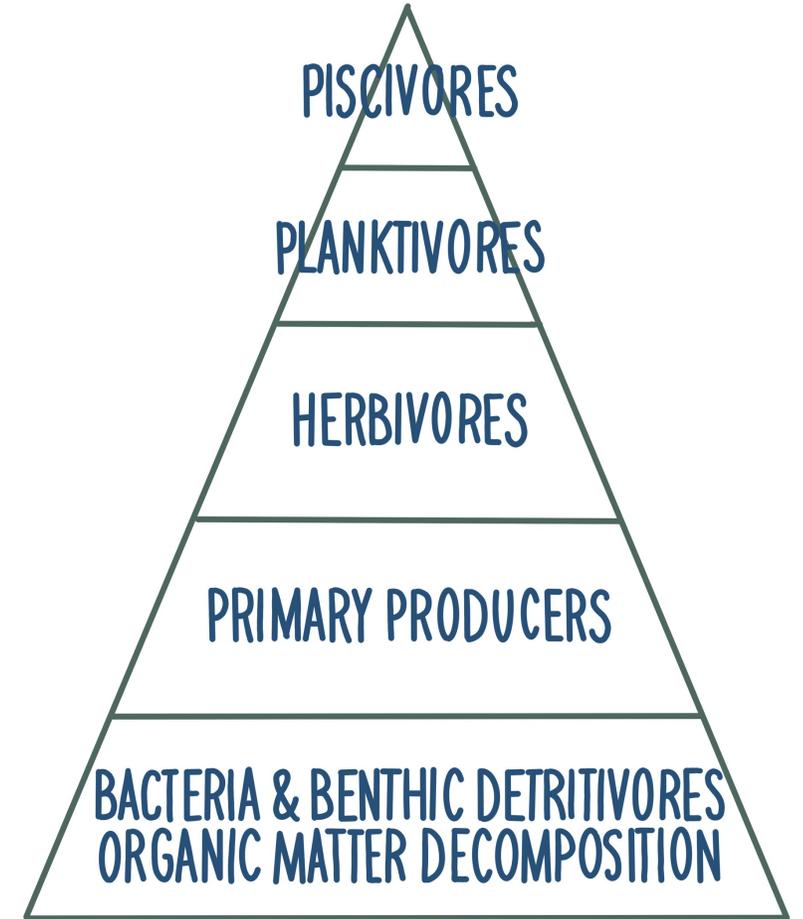

Bioindicators include biological processes, species, or communities and are used to assess the quality of the environment and how it changes over time.

# The Power of Periphyton

1. Base of aquatic food webs

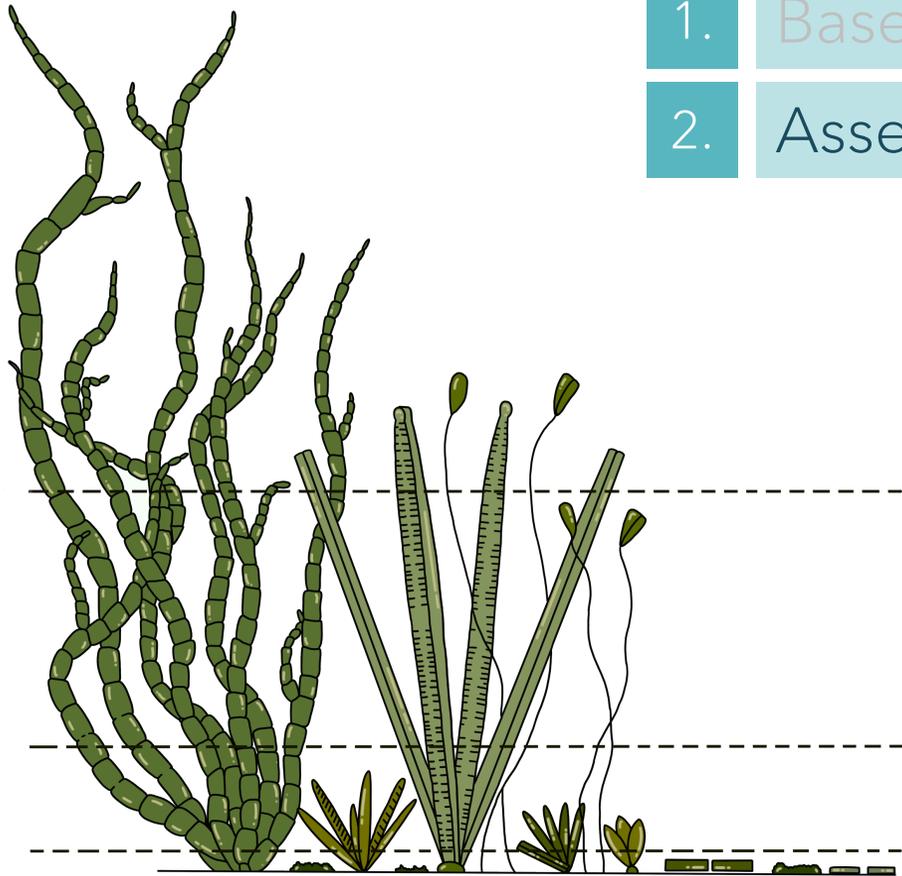

Modified from Hoagland et al. 1982

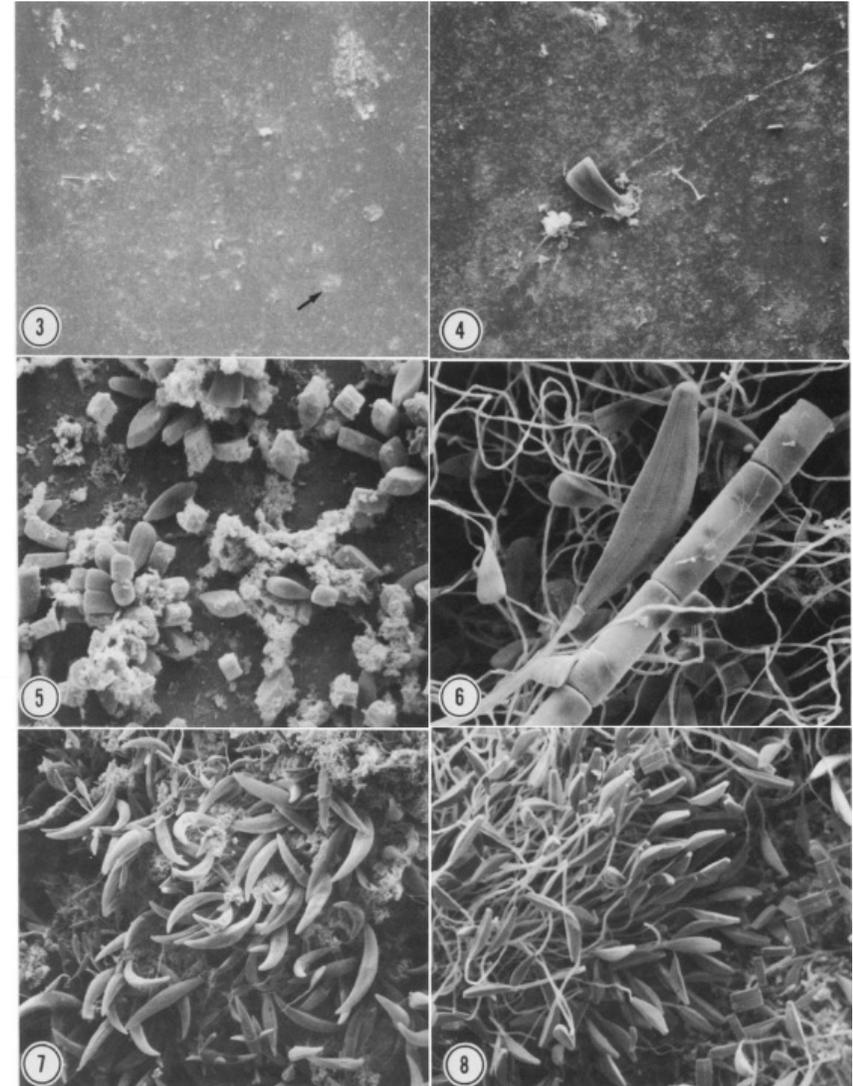

# The Power of Periphyton

1. Base of aquatic food webs
2. Assembles over time

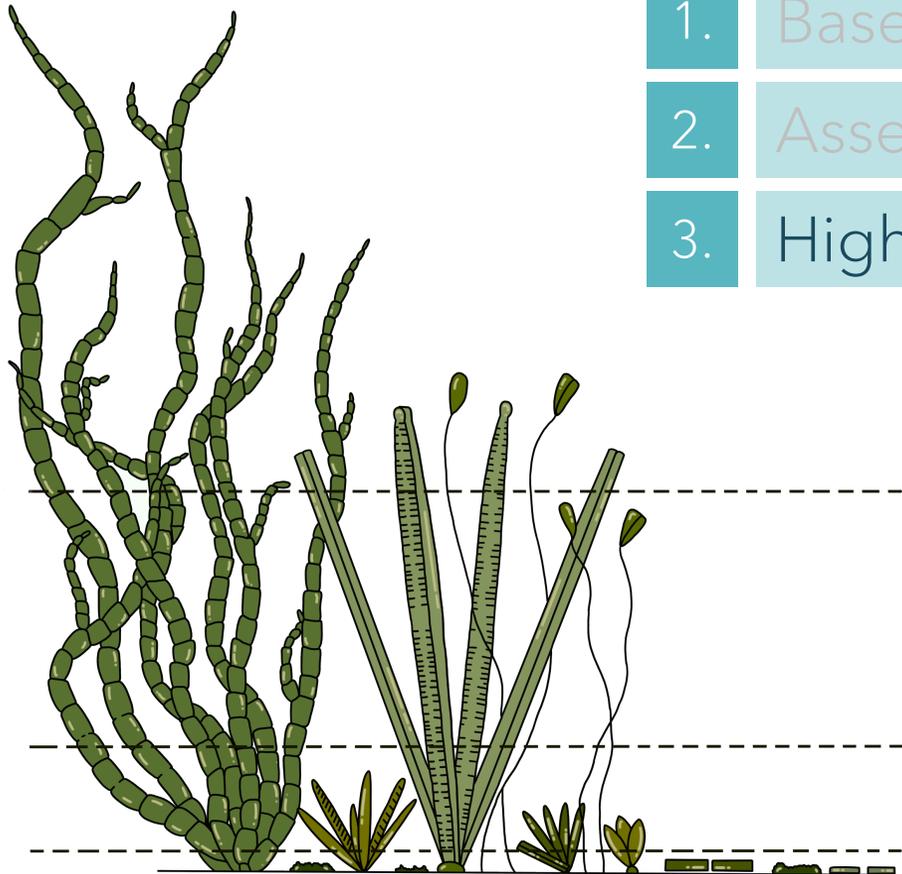

Modified from Hoagland et al. 1982

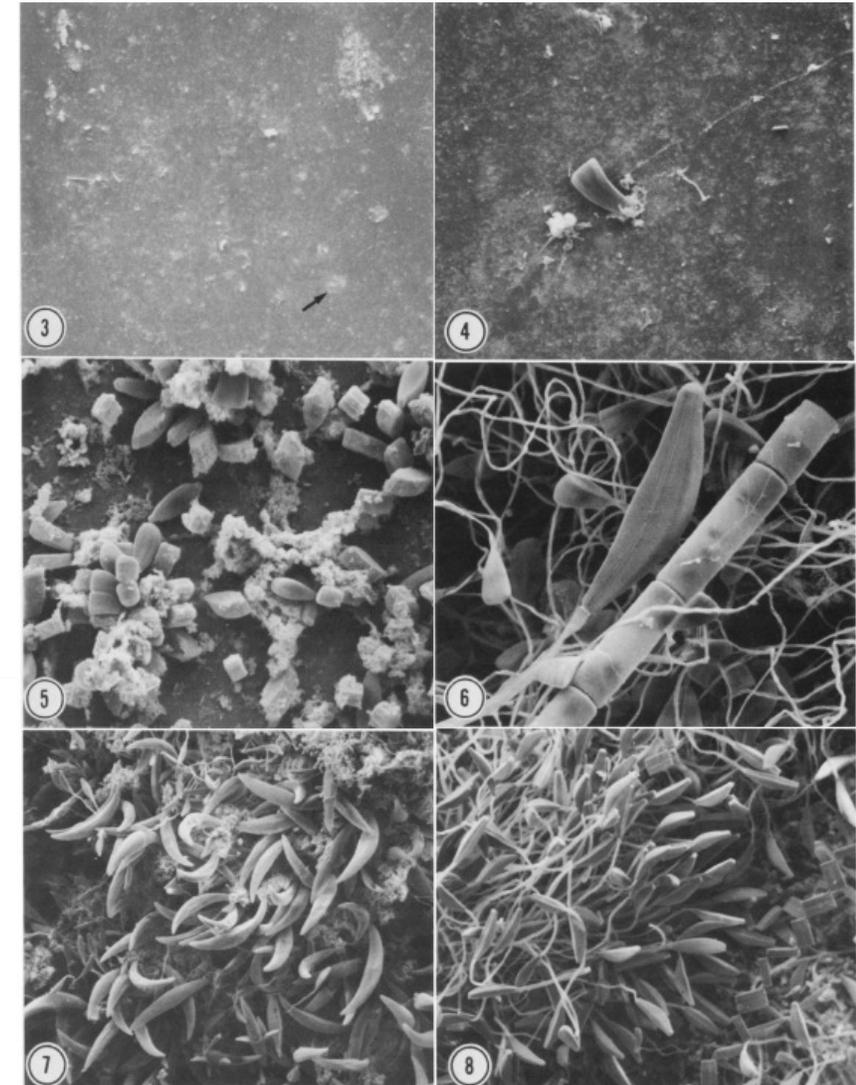

Periphyton growth across 4 weeks

# The Power of Periphyton

1. Base of aquatic food webs
2. Assembles over time
3. High species diversity

Modified from Hoagland et al. 1982

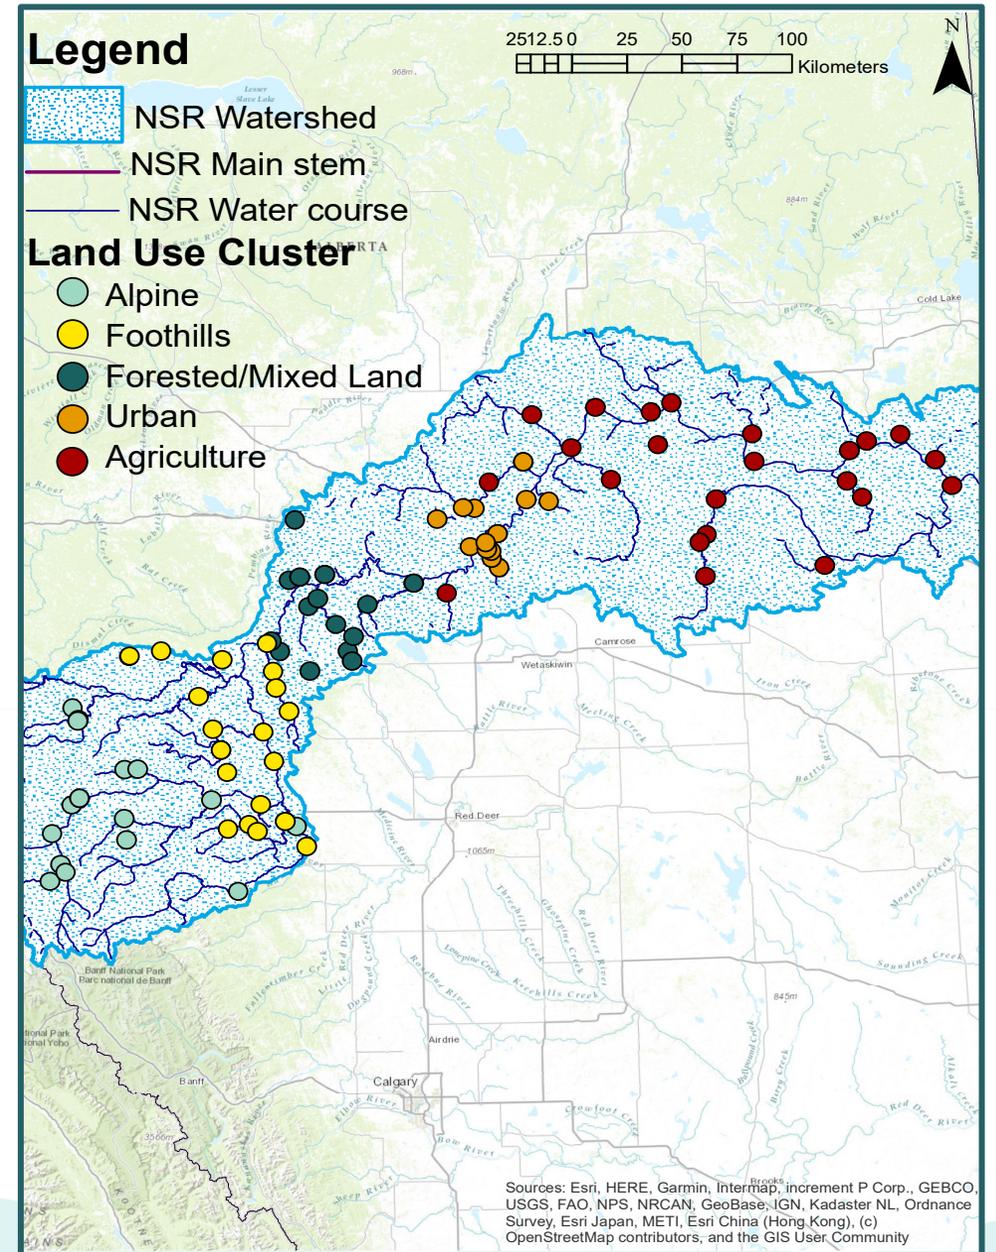

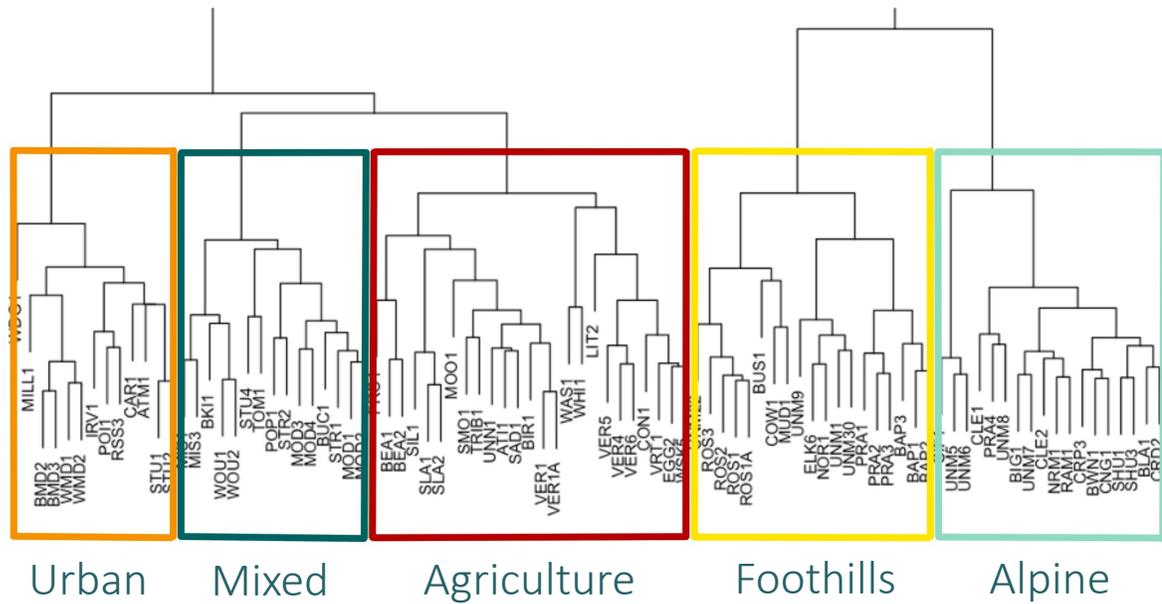

Periphyton growth across 4 weeks

Disentangle the influences of local and regional factors on benthic algal community structure in tributary streams of the North Saskatchewan River Basin.

Can regional land-use characteristics be used to reliably predict benthic algal community structure?

# Site Selection

Based on 63 geospatial variables we clustered our sites into 5 main land use clusters, and over the course of 3 years sampled a total of 93 sites.

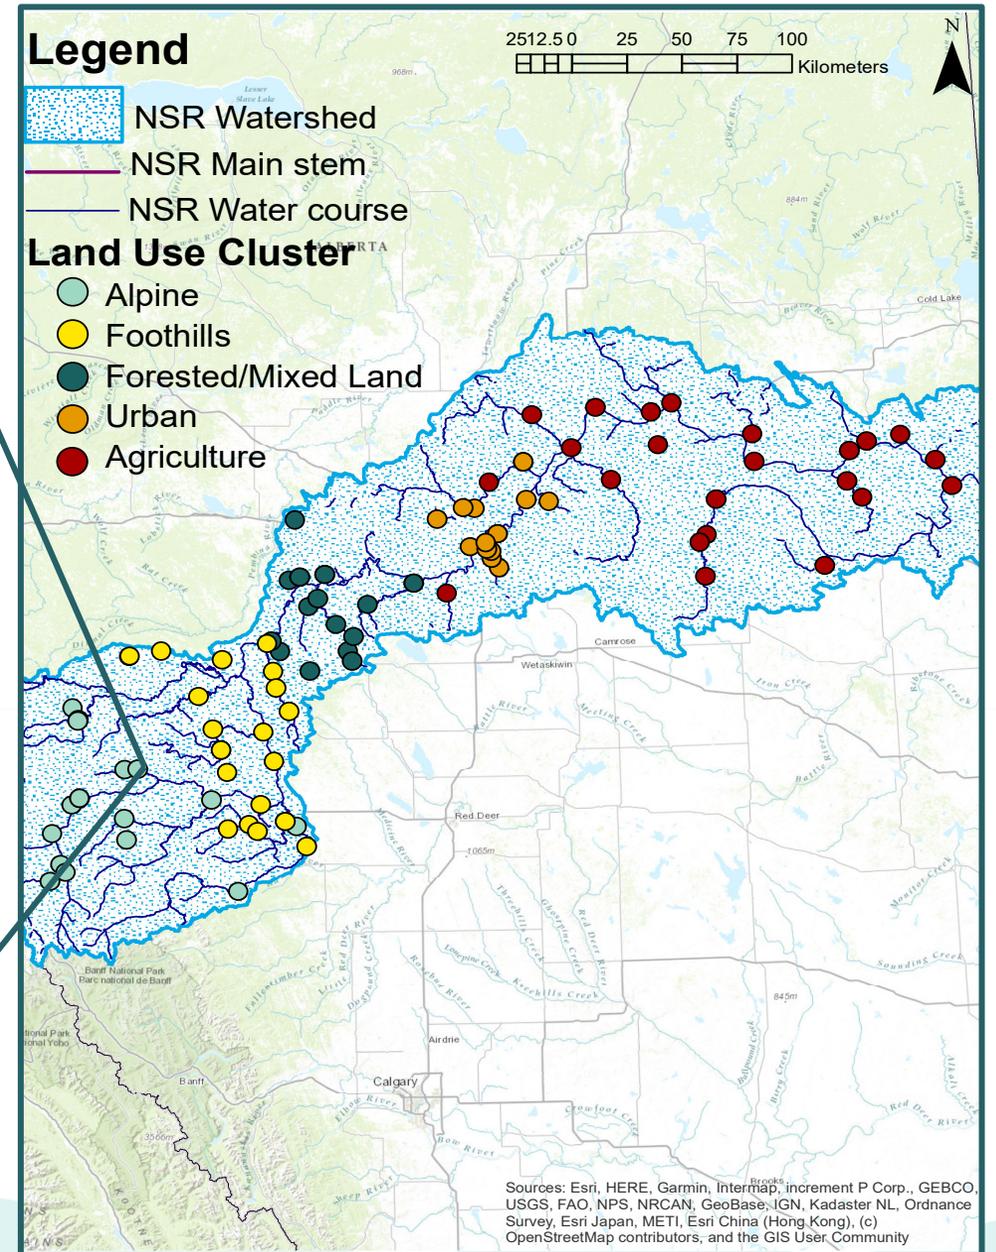

Created by Jillian Lightbown

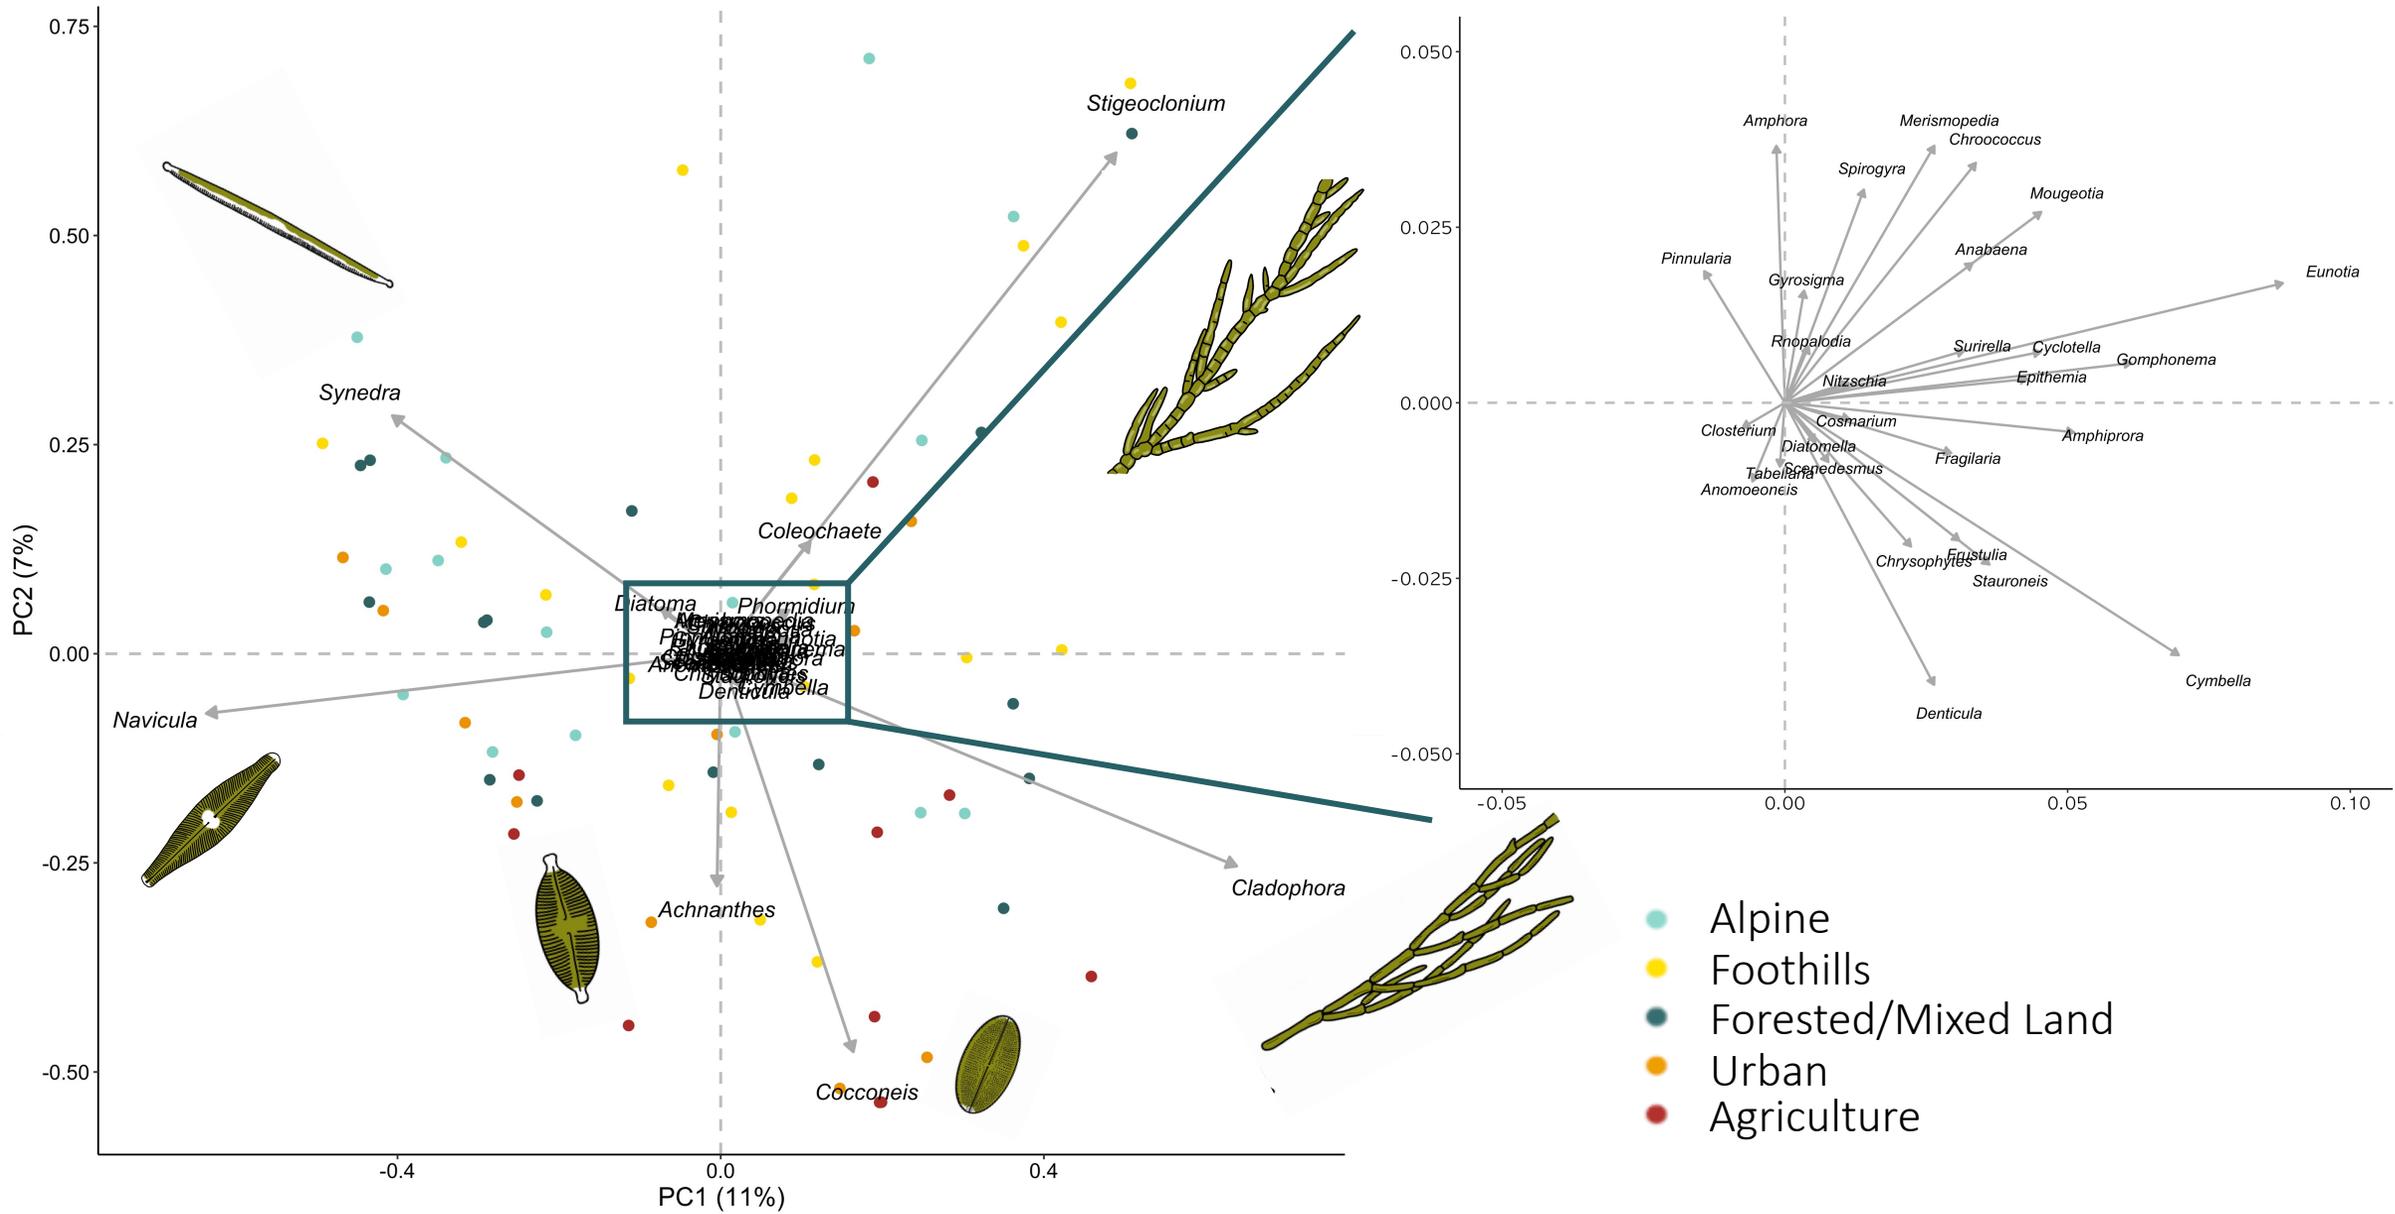

# Algal Collection

At each site, a total of 30 rocks were sampled:

- 10 for taxonomic analysis
- 10 for pigment analysis
- 10 for microbial analysis

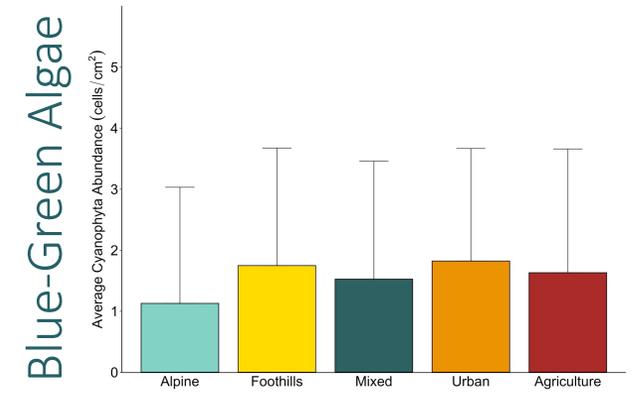

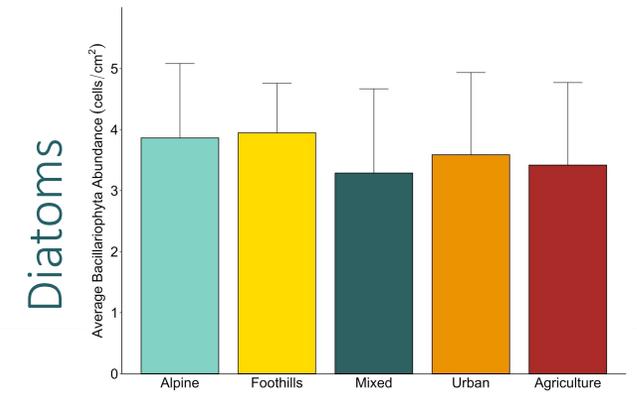

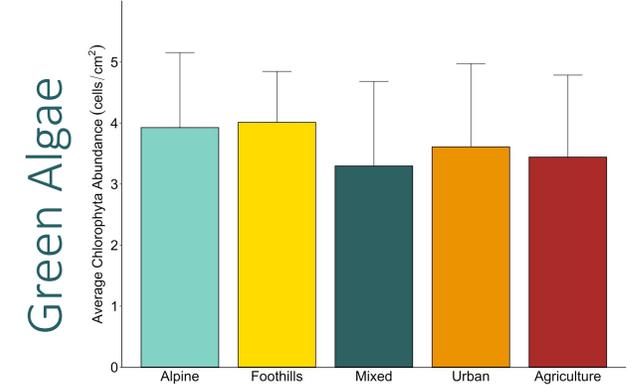

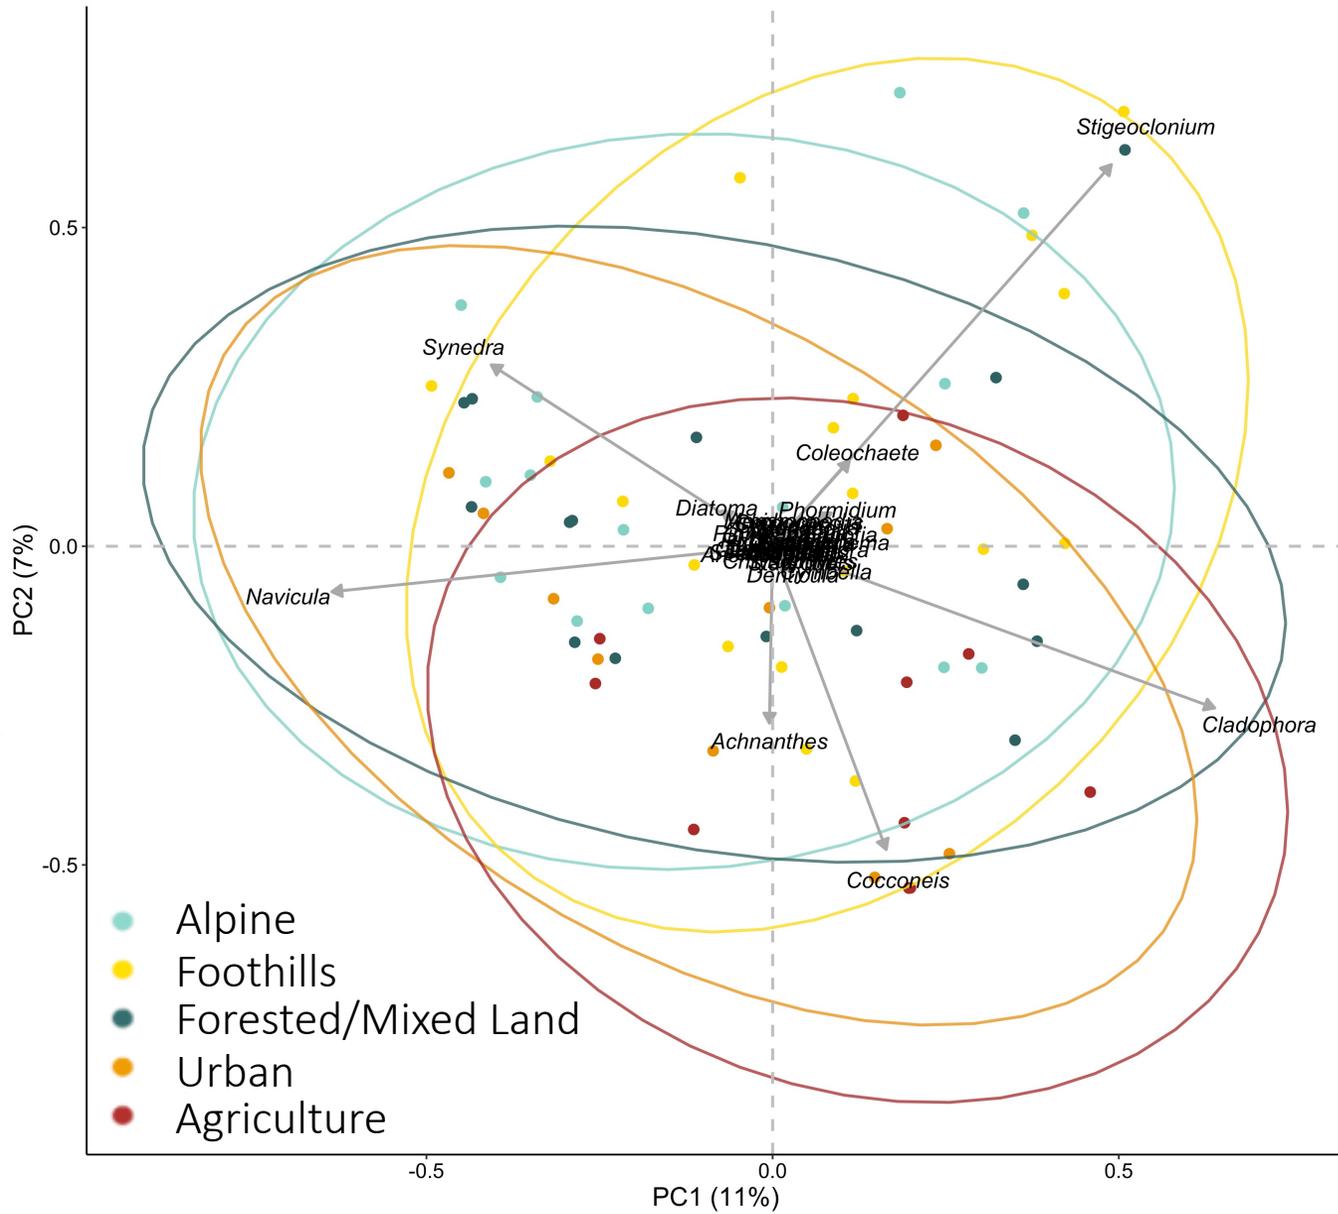

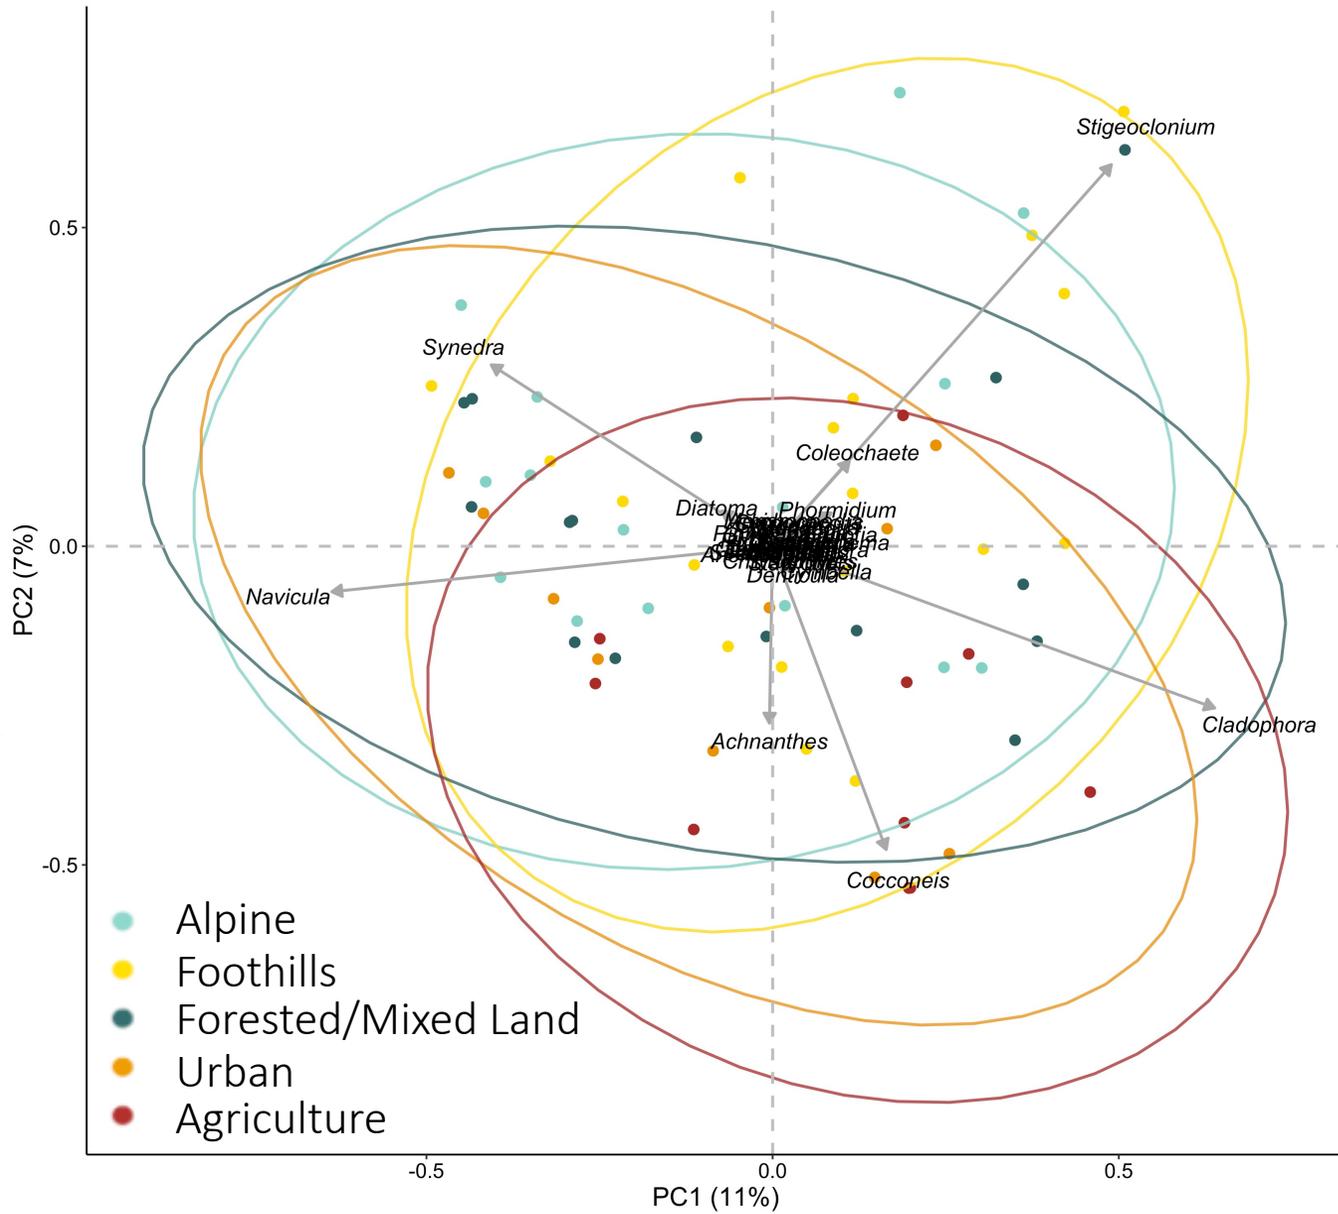

Created by Jillian Lightbown

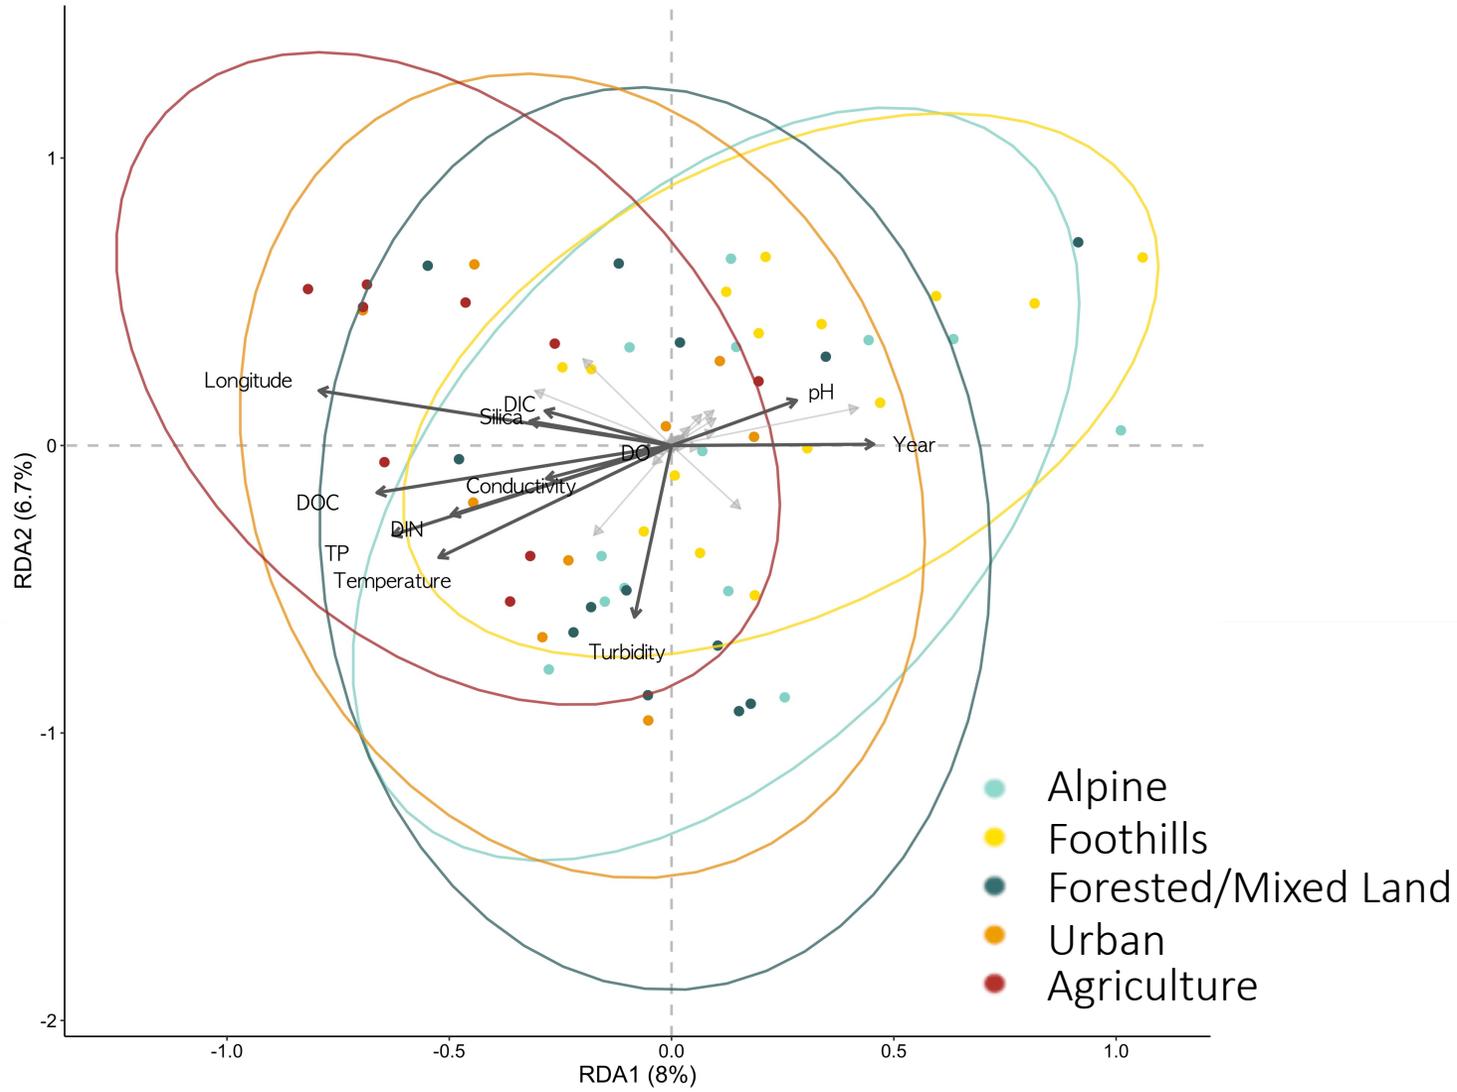

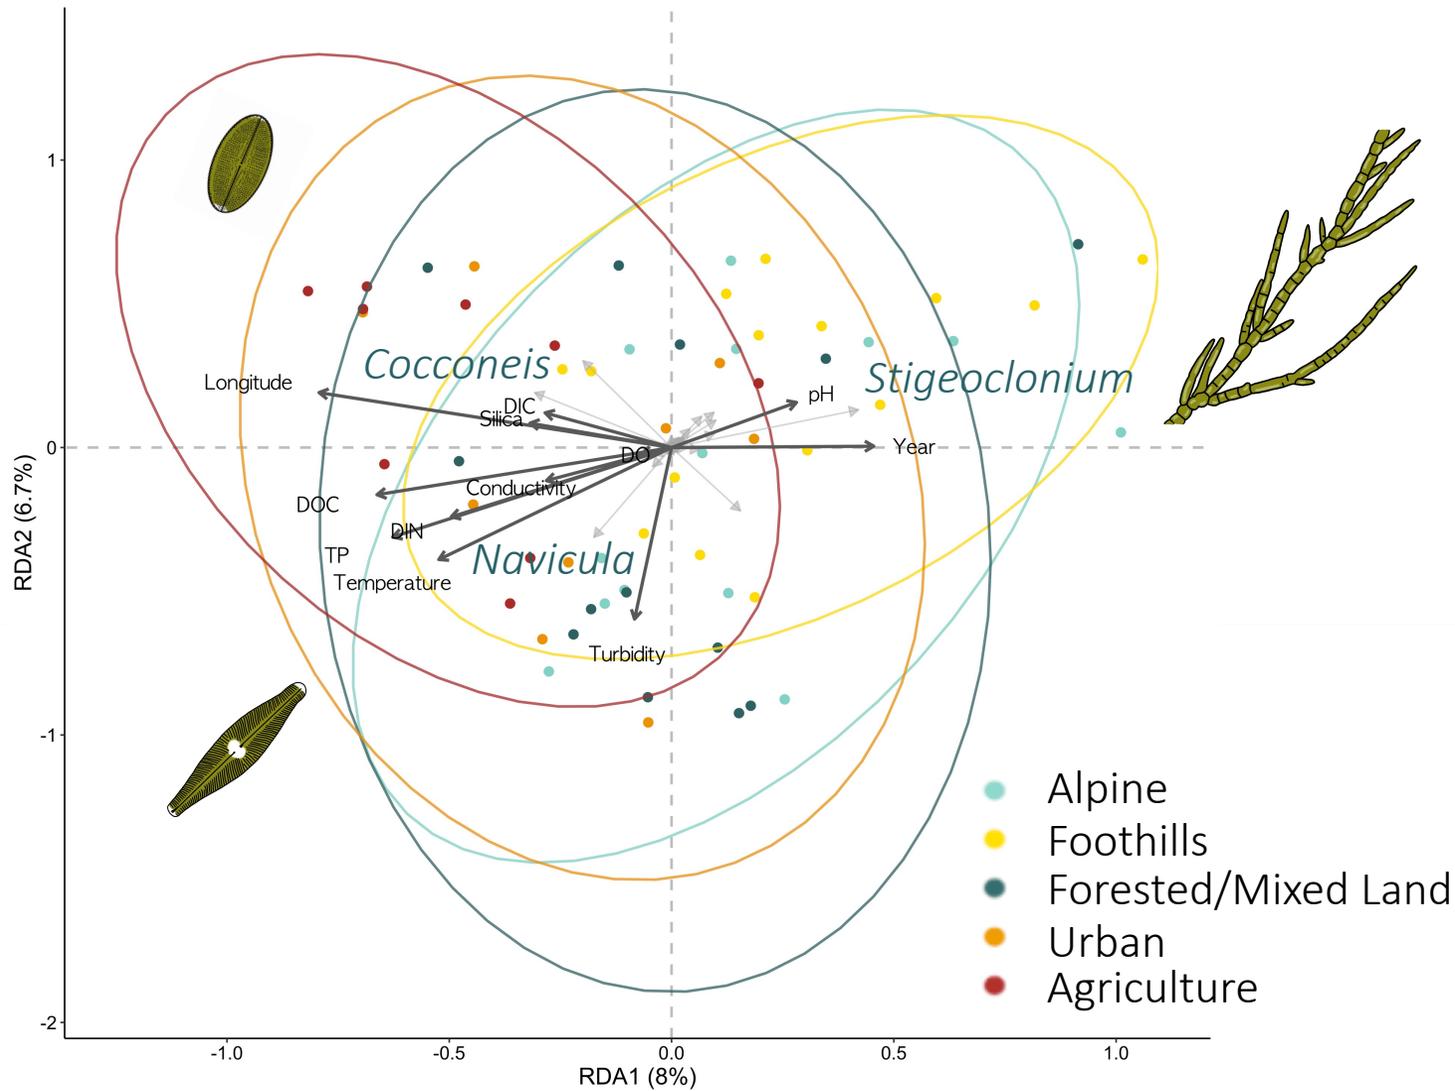

Regional factors, i.e., land use categories, can not reliably predict community composition.

Disentangle the influences of local and regional factors on benthic algal community structure in tributary streams of the North Saskatchewan River Basin.

Can regional land-use characteristics be used to reliably predict benthic algal community structure?

Can local factors (i.e. water chemistry) help elucidate the pattern behind benthic algal community structure?

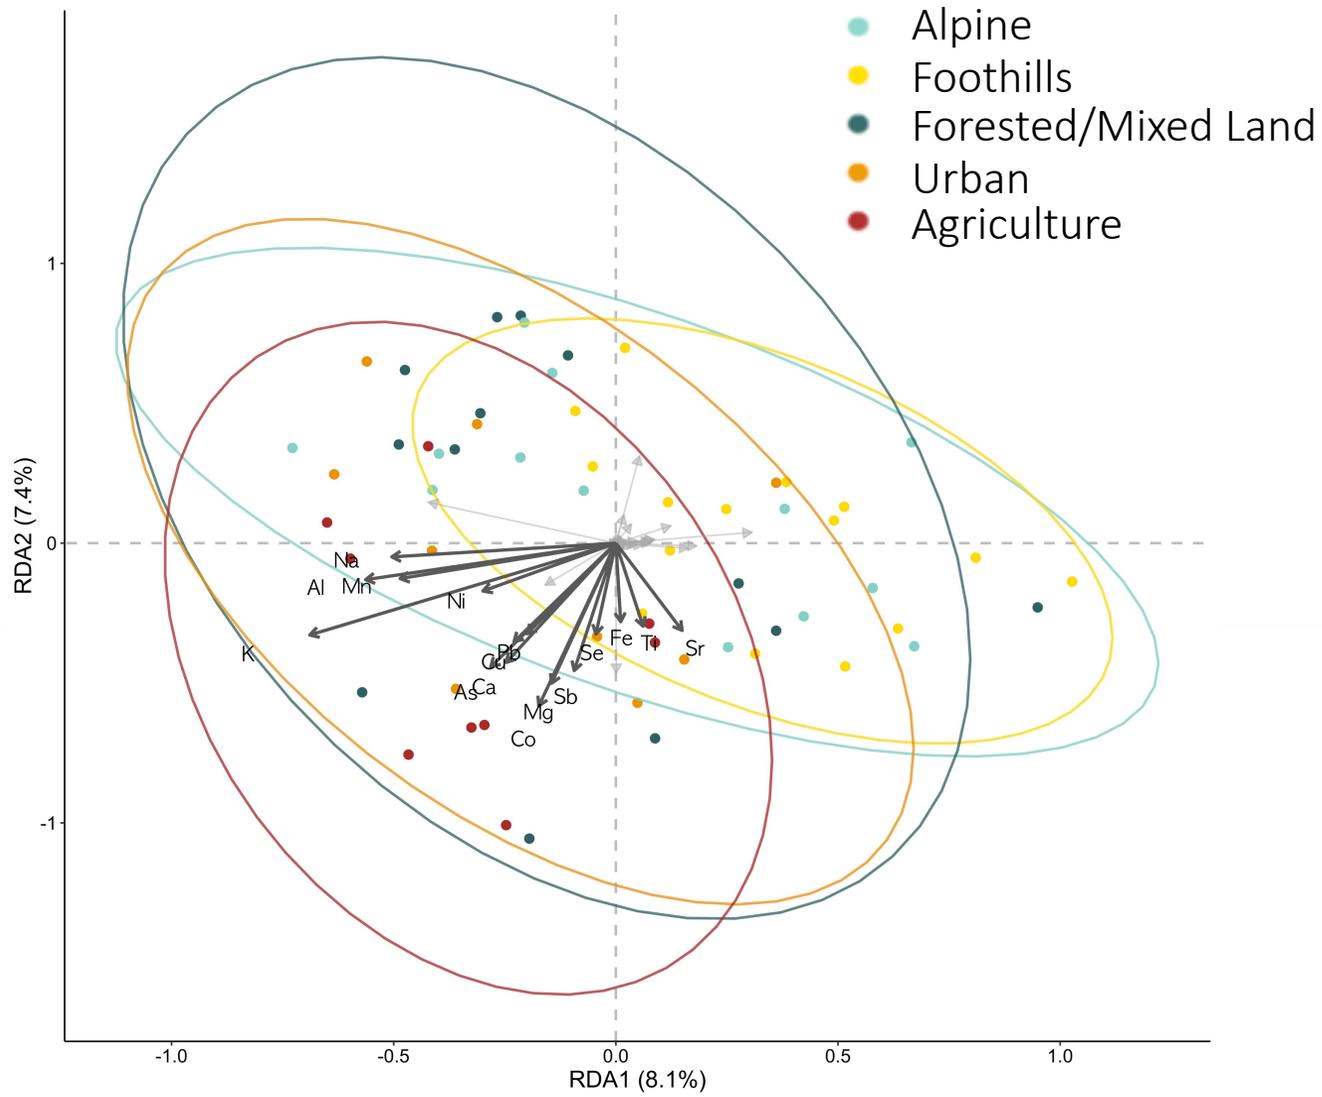

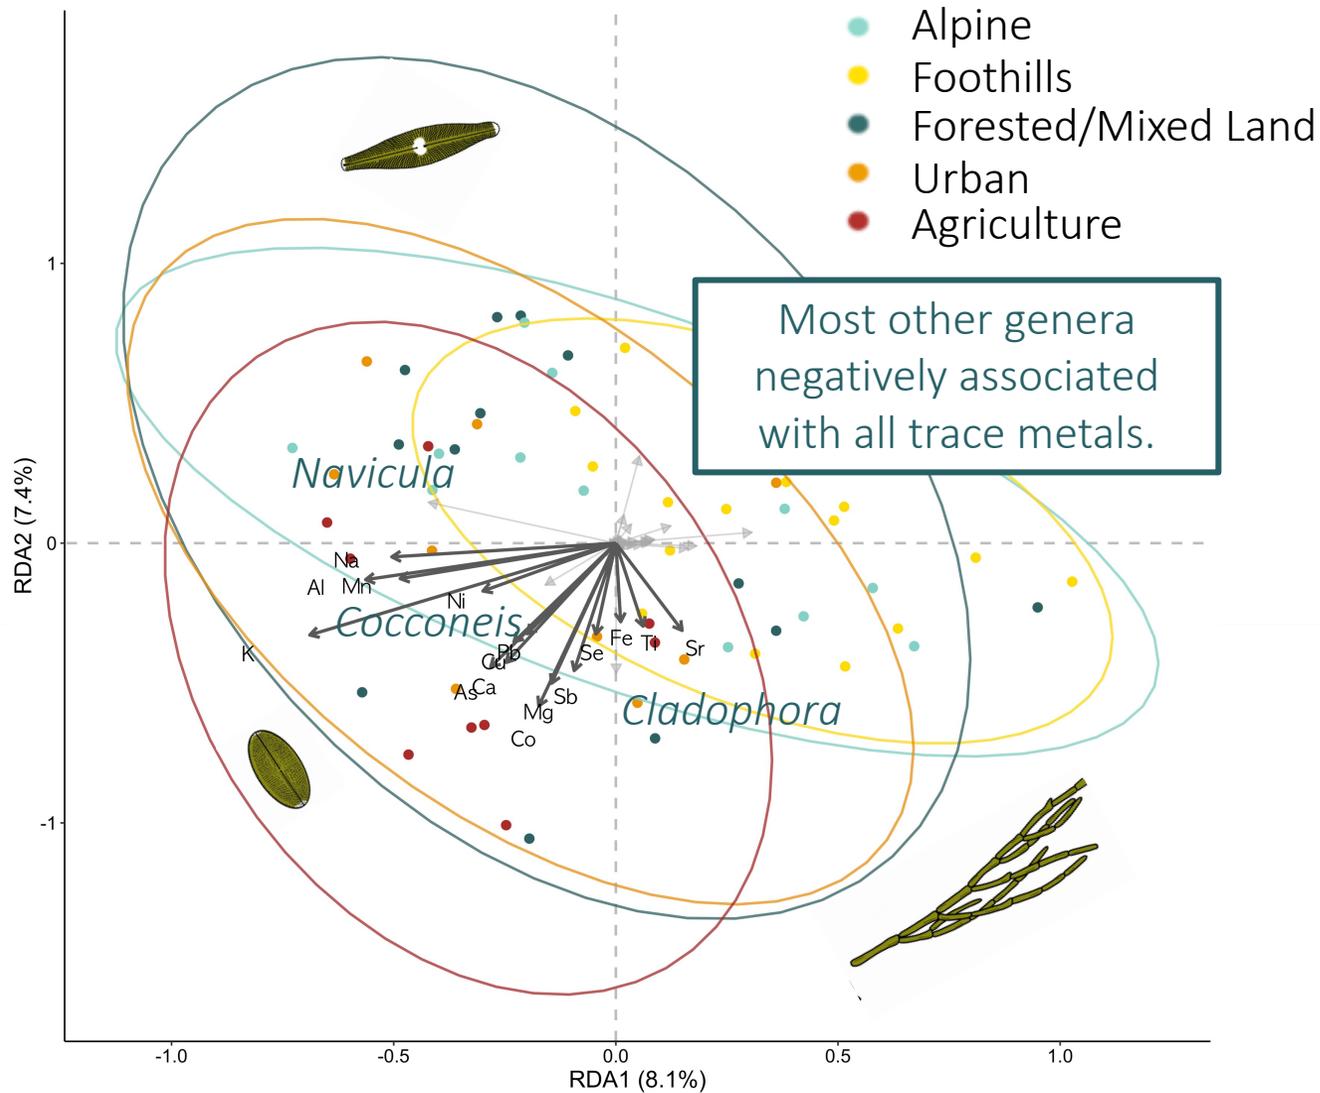

*Stigeoclonium* sp.: positively associated with an increase in pH, and negatively associated with increasing nutrients and temperature, higher abundance in foothills and alpine sites.

*Navicula* sp.: positively associated with an increase in turbidity, temperature and nutrients (nitrogen and phosphorus).

*Cocconeis* sp.: positively associated with dissolved inorganic carbon and silica, higher abundance in agricultural land use sites.

*Cladophora sp.*: positively associated with an increase in Iron (Fe), Selenium (Se), and Titanium (Ti).

*Navicula sp.*: positively associated with an increase in Sodium (Na), Aluminum (Al), and Manganese (Mn).

*Cocconeis sp.*: positively associated with an increase in Nickel (Ni), Potassium (K), Lead (Pb), and Copper (Cu).

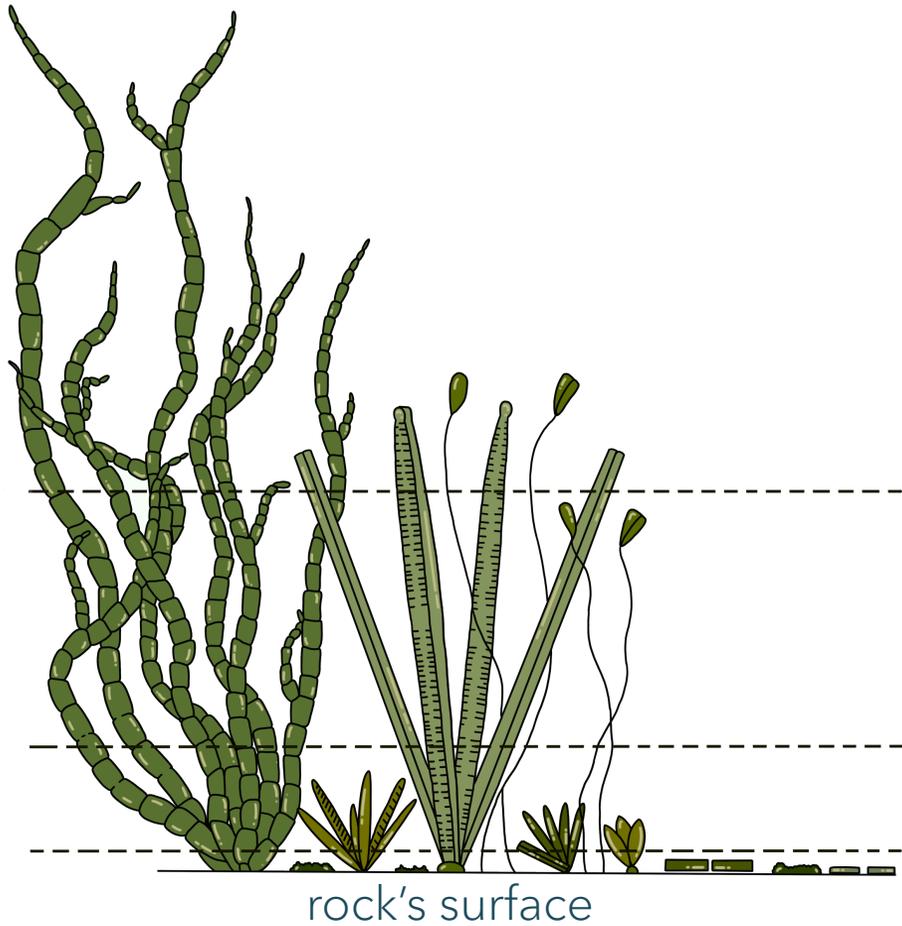

Disentangle the influences of local and regional factors on benthic algal community structure in tributary streams of the North Saskatchewan River Basin.

Can regional land-use characteristics be used to reliably predict benthic algal community structure?

Can local factors (i.e. water chemistry) help elucidate the pattern behind benthic algal community structure?

How are these changes in community structure impacting ecosystem function?

# The Functional Frontier

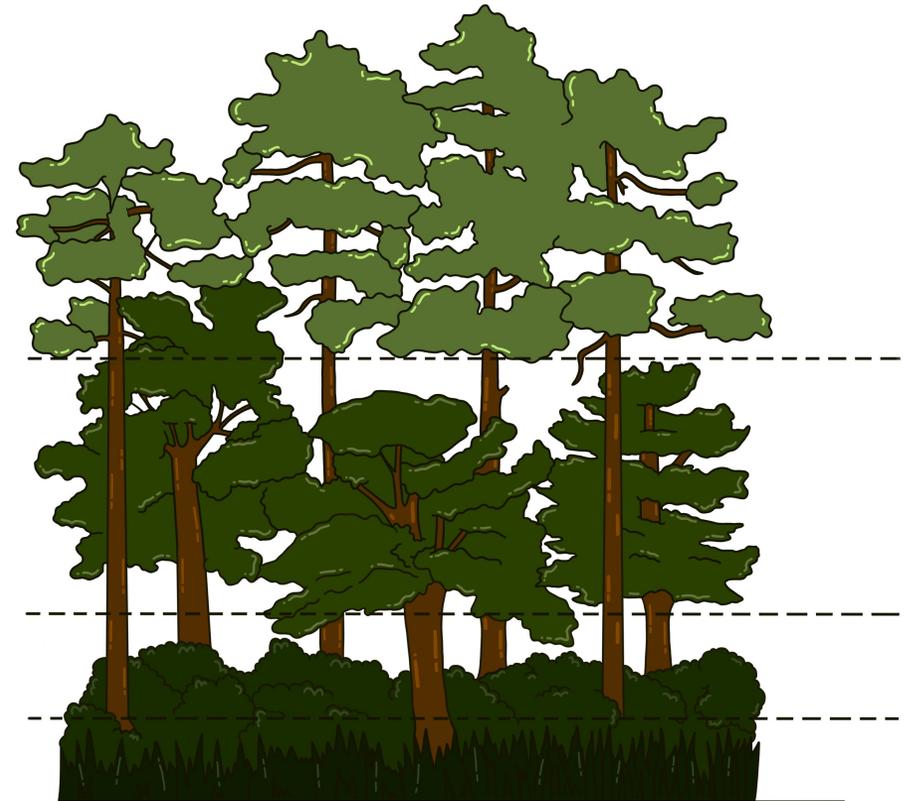

canopy layer

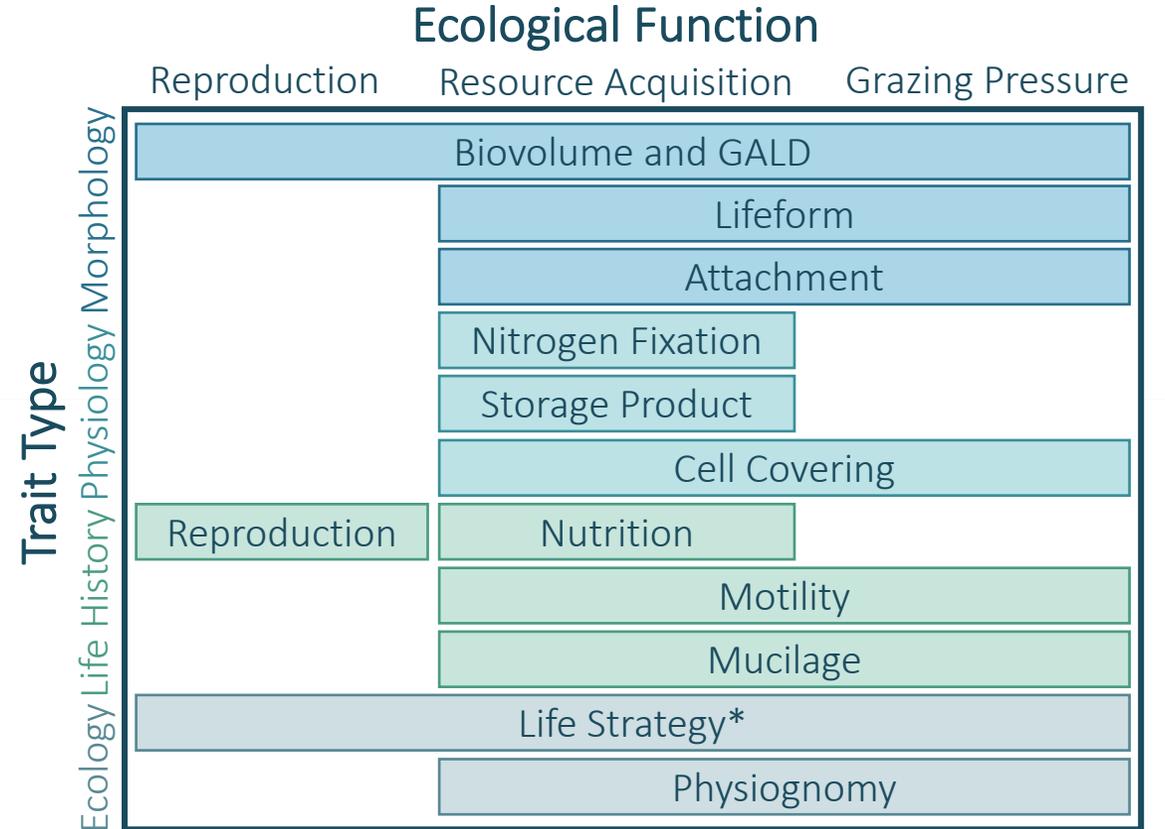

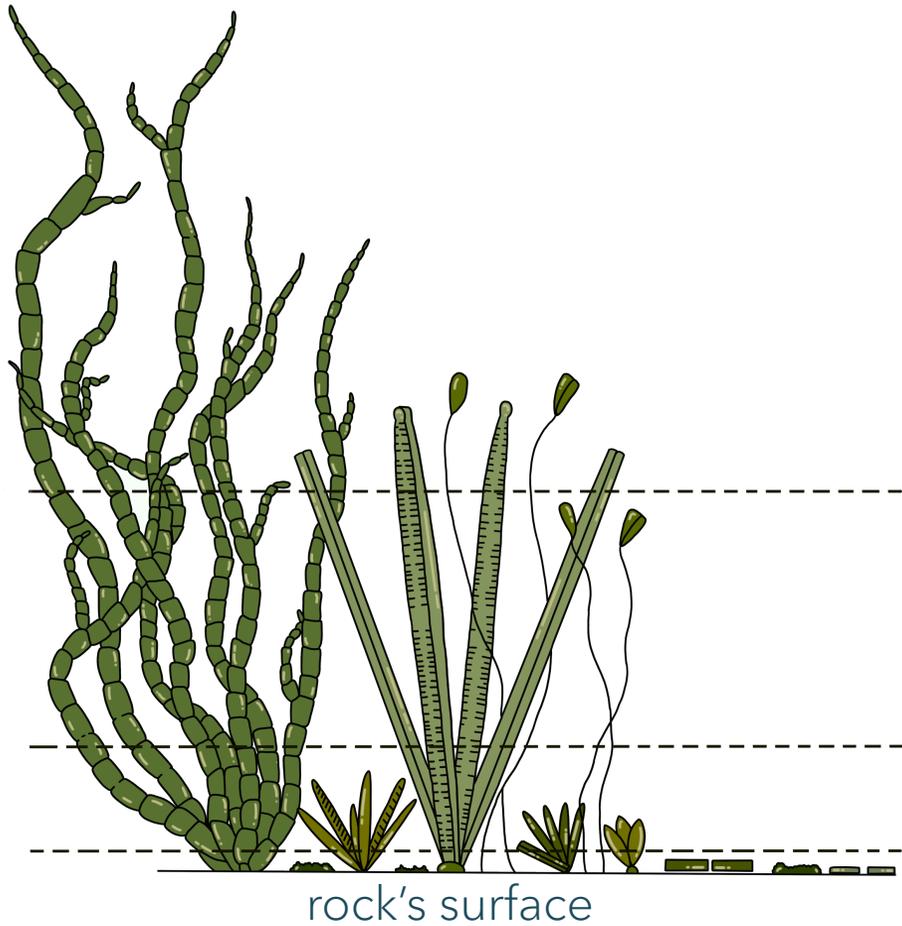

midstory layer

shrub layer

ground cover

# The Functional Frontier

Modified from Litchman and Klausmeier 2008

# *In Summary ...*

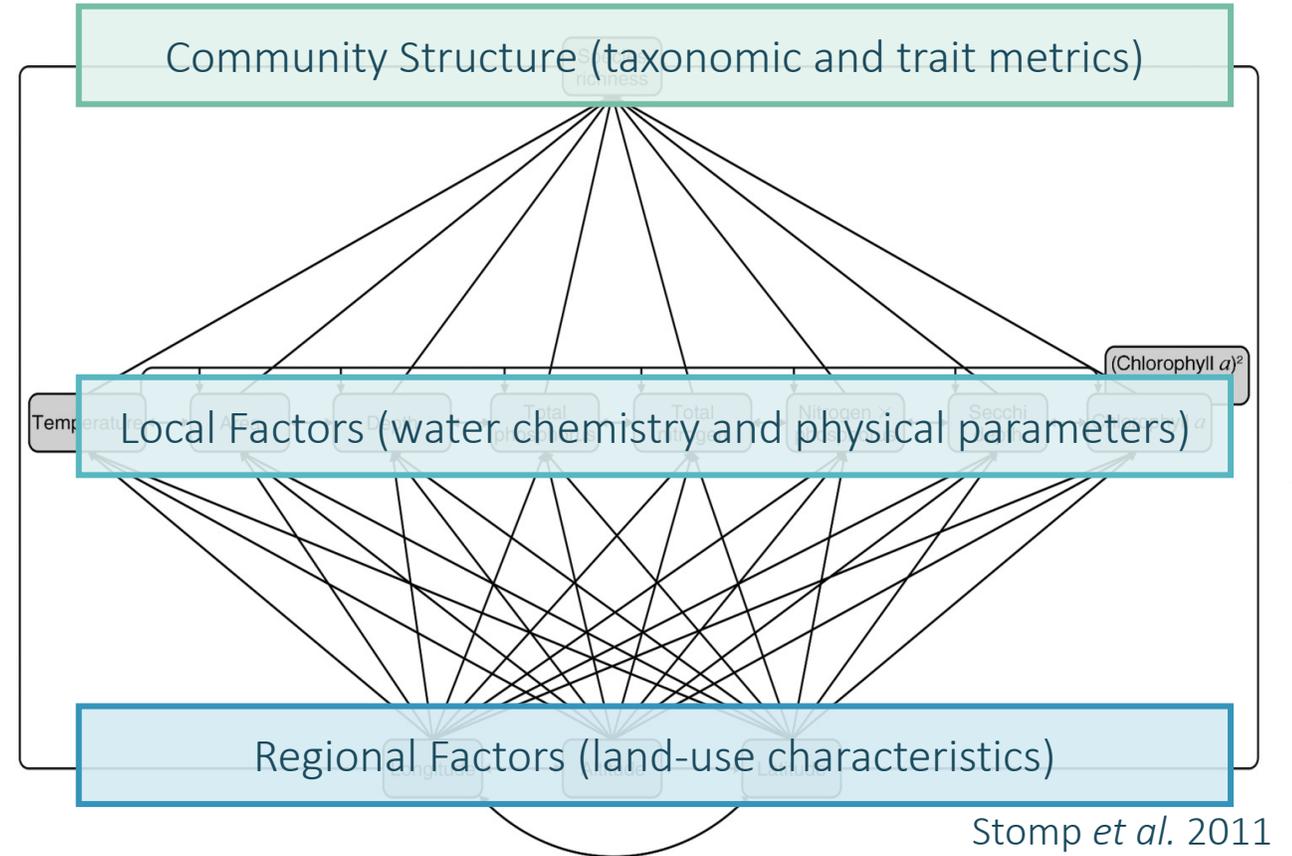

Regional factors can not be used to reliably predict community structure, but with the addition of local factors, such as water chemistry, we can start to see some patterns in community structure.

Categorizing how algal communities are structured across the NSR is essential for us to determine any changes that occur in the future.

# In Summary ...

Next steps for the project include:

- Finalize trait data and assess how they are changing across the watershed.
- Analyzing rare occurrence genera separately from high abundance genera.
- Assess the association between regional and local factors to determine if there are **indirect effects** .
